Notice of opposition shall be filed in a written reasoned statement. It shall not be deemed to have been filed until the opposition fee has been paid. (Art. 99(1) European Patent Convention).

THIS PAGE BLANK (USPTO)

Description

The present invention relates to an image processing apparatus and method for converting image data to be outputted to a recording device such as a laser-beam printer, and more particularly, to an image processing apparatus and method for converting the dot density of input image data when the dot density of the input image data is different from the recording dot density of a printer engine.

In recent years, a laser-beam printer is widely used as output device of a computer. Especially, a lower-density (e.g., 300 dpi) laser-beam printer is rapidly becoming popular with the merits such as compact size and low cost.

As shown in Fig. 1, a laser-beam printer for 300 dpi (dot per inch) recording density consists of a printer engine 51 and a printer controller 52. The printer controller 52, connected to the printer engine 51, receives a code data from a host computer 54, makes page information consisting of dot data in accordance with the code data and sends the dot data to the printer engine 51 in sequence. The printer engine 51 forms an electrostatic latent image on an electrostatic drum in accordance with the dot data. The latent image is transferred to a recording paper.

The host computer 54 loads an application program from a floppy disk 55 having the application program. The application program is then started, the host computer acts as, e.g., a word processor.

Since various application programs are nowadays produced, a user is able to make a lot of data and preserve them using these application programs.

On the other hand, a printer engine has been improved for the purpose of higher printing quality. Printer engines adapted to a recording density of 600 dpi or more than 600 dpi have been provided. A printer controller connected to such high-density printer engine has a data memory having a capacity corresponding to its recording density (for example, a printer connected to a printer engine for 600 dpi recording density has a memory capacity four times as large as 300 dpi).

Since most application programs are produced for printers having a lower recording density, they can not be used for printers with a higher recording density.

For example, Figs. 2 and 3 respectively show the dot pattern of letters "G" and "t" for 300 dpi recording density . If these letters are recorded in 600 dpi recording density, the size of these letters is halved in both length and in width.

By adopting a known data interpolation method to the above case, the pattern data for 300 dpi can be converted to a dot pattern for 600 dpi, where the length and width of the pattern data for 300 dpi are simply doubled and applied as a pattern data for 600 dpi structure. This method avoids diminishing the size of letters (Figs. 4 and 5). However, after the pattern conversion, the jagged edges of the outline portion of the letters remains the same as the jagged edges in Figs. 2 and 3. This means that it is impossible to take advantage of the high quality 600 dpi printer engine.

Another data interpolation method is known as the smoothing technique, where the jagged edges of image data are detected and smoothed. This technique can improve the quality of the image data of characters and figures having at least two continuous dots. However, the technique can not obtain the same effect when recording picture images processed by the dither method, error diffusion method and the like.

Generally, in an image data processed in a half-tone processing method such as the Dither method and the error diffusion method, in light portions, a black dot whose size is smaller than one dot (300 dpi for 300 dpi printer engine) can not be printed, and a white dot smaller than one dot can not be printed in dark portions. Consequently, the printed image quality of the light portions and the dark portions is lower than that of.the neutral density portions.

Fig. 6 shows an example of a fattening type gray scale pattern. Fig. 7 shows an example of a light portion of a half-tone image printed using the gray scale pattern, and Fig. 8, an example of a dark portion of a half-tone image printed using the same. In these examples, isolated dots are expressed as scattered specks, and even if those dots are printed in higher recording density, the size of the smallest speck is the same as the size of a dot in 300 dpi. Therefore, this method can not improve the quality of printed half-tone images.

EP-A-0356224 describes an image processing apparatus wherein smoothing means are provided to smooth jagged edge portions by interpolating pixel data when first image data is converted into second image data of higher resolution or recording density than the first image data.

According to one aspect of the present invention, there is provided an image processing apparatus in accordance with claim 1.

The present invention also provides an image processing method in accordance with claim 11.

An embodiment of the present invention provides an image processing apparatus and method capable of the high-quality recording of picture images expressed by half-tone processing method, as well as smoothed images of characters and figures, when image data for lower recording density is converted for higher recording density. More particularly, an embodiment of the present invention improves the gradation of image data by detecting a predetermined pattern scattered in a pattern data of lower recording density (e.g. 300 dpi) and diffusing them in the dot pattern of higher recording density (e.g. 600 dpi).

Other advantages besides those discussed above shall be apparent to those skilled in the art from the description of a preferred embodiment of the invention which follows. In the description, reference is made to the accompanying drawings, which form a part thereof,

and which illustrate an example of the invention. Such example, however, is not exhaustive of the various embodiments of the invention, and therefore reference is made to the claims which follow the description for determining the scope of the invention.

DETAILED DESCRIPTION OF THE PREFERRED EMBODIMENTS

Preferred embodiments of the present invention will be described in detail with reference to the accompanying drawings.

[First Embodiment]

In the first embodiment, described is an image recording apparatus having a data conversion circuit shown in Fig. 9 for dot conversion inserted between the printer controller 52 and the printer engine 51 (Fig. 1). Since the data conversion circuit is illustrated as a part of the printer engine 51 in this embodiment, it can be also a part of the printer controller 52. In this embodiment, the printer controller 52 sends an image signal for the recording density of 300 dpi, while the recording density of the printer engine 51 is 600 dpi. The data conversion circuit converts the resolution of the image signal so as to match the recording density of the printer engine 51. The printer engine 51 includes a laser driver which modulates a laser beam in accordance with the image signal (dot information), a scanner for scanning the beam and an electrostatic drum, as known to those skilled in the art.

The printer controller 52 sends an image signal VDO for the recording density of 300 dpi and an image clock VCLK to the data conversion circuit in response to a horizontal synchronous signal HSYNC supplied from a horizontal synchronous signal generator 4 in the data conversion circuit. The horizontal synchronous signal generator 4 sends the horizontal synchronous signal in accordance with a well-known BD (beam detection) signal output by the printer engine 51 as a synchronous signal in a main scanning direction.

The printer engine 51 receives a laser driving signal LD for recording density of 600 dpi from the data conversion circuit. the LD signal is made from the image signal VDO for recording density of 300 dpi and the image clock VCLK, and the printer engine 51 records an image in recording density of 600 dpi.

Fig. 9 is a block diagram which shows the construction of the data conversion circuit according to the first embodiment of the present invention. In Fig. 9, a frequency doubler 1 doubles the frequency of the image clock VCLK and obtains a clock VCLK' having the doubled frequency as that of VCLK. An oscillator 5 generates a clock LCLK whose frequency is quadruple of that

of the image clock VCLK. A demultiplexer 2 selects one of line memories 6 to 10 and supplies the image signal VDO to the selected line memory. The horizontal synchronous signal generator 4 counts the BD signals and outputs one horizontal synchronous signal per two BD signals. A device controller 3 controls the line memories 6 to 10 per line in accordance with the BD signal. More specifically, the device controller 3 directs one of the line memories to write the image signal VDO in synchronizing with the clock VCLK', while the device controller 3 directs the other four line memories to read out the image signal synchronically with the clock LCLK. During the writing operation to one of the line memories, the reading out operation from the other four line memories is performed twice . The device controller 3 alternatively carries out the writing and reading out operations as follows. When the writing operation is performed to the line memory 6, the reading out operation is performed to the line memories 7 to 10. At the next timing, the writing operation is performed to the line memory 7 and the reading out operation is performed to the line memories 8, 9, 10 and 6.

At the next timing, the image signal VDO is written into the line memory 8, while the contents of the line memories 9, 10, 6 and 7 are read out.

Each of the line memories 6 to 10 has a capacity for image data corresponding to recording density of 600 dpi in a main scanning direction, twice as large as that for image data of 300 dpi in the main scanning direction. As the writing operation into each line memory is synchronized with the clock VCLK' having the doubled frequency of the image clock VCLK, dot information of 300 dpi is doubled in the main scanning direction and written into these line memories. The dot information of 300 dpi can be stored in the line memories as dot information of 600 dpi.

Each of signals D1 to D5 is a read out signal from each of the line memories 6 to 10 respectively. A selector 13 selects four signals of the read out signals D1 to D5 which are read from line memories under reading operation, and divides them into predetermined outputs DS1 to DS4. A four bit demultiplexer 14 alternatively outputs the output signals DS1 to DS4 from the selector 13 to a decision circuits 15 or 16 (DCT 15 or 16) at every BD signal. the decision circuits 15 and 16 compare the input image data for four lines (DS1 to DS4) and output signals Q1 or Q2 based on the comparison result. A line memory 11 stores the signal Q1 and a line memory 12 stores the signal Q2. The memory capacity of the line memories 11 and 12 is the same as that of the line memories 6 to 10. The clock LCLK is used in the writing and reading out operations of the line memories 11 and 12. A selector 17 selects an output signal D6 read out of the line memory 11 or an output signal D7 read out of the line memory 12, and outputs the selected signal as the laser driving signal LD.

The device controller 3 also controls the writing and reading out operations at the line memories 11 and 12,

the selecting operation to the demultiplexers 2 and 14, and the selectors 13 and 17. The decision circuits 15 and 16 receives a logical selection signal SEL. The logical selection signal can be utilized, for example, in the structure where the host computer 54 sets the SEL signal in accordance with the type of image data to change over logics for data interpolation.

The operations in the structure in Fig. 9 will be described with reference to the timing chart shown in Fig. 10.

As described above, when the demultiplexer 2 selects the line memory 6, the writing operation is performed at the line memory 6. While an image signal VDO for one line is written into the line memory 6 in synchronizing with the clock VCLK', the image signals for each one line stored in the line memories 7 to 10 are read out twice, synchronically with the clock LCLK. In this case, each of the output signals DS1 to DS4 is D5, D4, D3 and D2 in turn. The first output signals DS1 to DS4 from the selector 13 are input into the decision circuit 15 via the demultiplexer 14, and the data Q1 is written into the line memory 11 after a predetermined processing time. The writing and reading out operations to the line memories 11 and 12 are performed alternately. When the writing operation is carried out to the line memory 11, the reading out operation is performed at the line memory 12. The selector 17 outputs the data D7 read out of the line memory 12 as the laser driving signal LD.

On the other hand, when the second reading out operation is performed to the line memories 7 to 10, the data DS1 to DS4 are input into the decision circuit 16 via the demultiplexer 14, and after a predetermined processing time, the data Q2 is written into the line memory 12. The selector 17 outputs the data D6 read out of the line memory 11 as the laser driving signal LD.

Fig. 11 is a block diagram showing the structure of the decision circuit 15 (16) in the first embodiment. In Fig. 11, seven bit shift registers 18 to 21 receive the input signals DS1 to DS4. A logical circuit 22 (23) receives the data output from the shift registers 18 to 21 and carries out a logical operation. More specifically, the logical circuit 22 (23) receives each output from the shift registers 18 to 21, and after a predetermined processing, outputs as the output signal Q1 (Q2). The processings at the decision circuits 15 and 16 are different and are described below.

Figs. 12A to 12 C and Figs. 13A and 13B show the logical operations at the logical circuit 22 (23) according to the first embodiment.

As shown in Figs. 12B and 12C, when the SEL signal input into the logical circuit 22 (23) is "0", <logical expression 1> (Fig. 12B) is selected for the decision circuit 15, and when the SEL signal is "1", <logical expression 2> (Fig. 12C) is selected for the decision circuit 15.

In this embodiment, the logical expressions for the logical circuit 23 in the decision circuit 16 are given in Fig. 13B. The logical expression in Fig. 13B has no relation with the SEL signal.

In the decision circuit 15, when SEL = 0 holds, a jagged edge portion of the image data is detected and an interpolation data to smooth the jagged edge portion is generated. The interpolation operation in the case where SEL = 0 holds will be described below.

Fig. 12A illustrates the positional relation between an object pixel and peripheral pixels. The reference numerals of each pixel (1A, 1B, ...4G) correspond to those in the <logical expression 1> in Fig. 12B. Figs. 12A and 12B are correlated as the reference pixels and the corresponding logical expression in the interpolation in the data of an object pixel. Each of the pixels has a value of "1" or "0". The pixel with a value "1" is a black pixel, and the pixel with a value "0" is a white pixel. In Figs. 13A and 13B indicate the same correlation as in Figs. 12A and 12B.

In the decision circuit 16, an output signal Q is set in accordance with the logical expression in Fig. 13B and an interpolation data in the sub scanning direction is generated, which means the pixel between the lines (the pixel corresponds to the position between 2D and 3D) of an image data for recording density of 300 dpi is interpolated.

In the decision circuit 15, the data of 3D is newly set in accordance with the <logical expression 1> in Fig. 12B and thus an interpolation data in the main scanning direction is generated.

The logic for the interpolation of jagged edge portions in a sideward direction will be described below.

In Fig. 14A, if 2G and 3B to 3F are recording information indicating black pixels ("1") and 2A indicates a white pixel ("0"), the image data is determined as a pattern with a jagged edge portion and an object pixel Q is decided to be black for the smoothing of the jagged edge. The logical expression corresponding to this processing is given in Fig. 14B.

Similarly, in Figs. 15A and 16A, a jagged edge portion is detected and the object pixel Q is determined to be black. The corresponding logical expressions are given in Figs. 15B and 16B. The jagged edge portion in an image for recording density of 300 dpi as shown in Fig. 17A can be smoothed as shown in Fig. 17B, with the combination of the above logical expressions.

Regarding jagged edge portions symmetric along with the main scanning direction and the sub scanning direction, the logical expressions for the interpolation of the jagged edge portions in the sideward direction can be obtained by combining the similar logical expressions.

Next, the logic for the interpolation of jagged edge potions in the vertical direction (the sub scanning direction) will be described below.

In Fig 18A, if 4C and 1E to 3E are recording information indicating black pixels ("1") and 1C is a white pixel ("0"), it is determined that there is a jagged edge portion in the image and the object pixel 3D is determined to be black for the interpolation of the jagged edge. The corresponding logical expression is given in Fig. 18B. In

Figs. 19A and 20A, data interpolation is carried out in the similar manner, and the corresponding logical expressions are given in Figs. 19B and 20B. Regarding jagged edge portions symmetric along with the main scanning direction and the sub scanning direction, interpolation of the jagged edge portions in the vertical direction can be performed by combination of the similar logical expressions.

Next, the interpolation in the main scanning direction will be described. In Fig. 21A, the line including a pixel 3D is to be interpolated. When a jagged edge portion in the vertical direction is detected, the object pixel is determined to be black ("1"). As shown in Fig. 21A, if 4C, 2E and 3E are indicating black pixels ("1") and 2C is a white pixel ("0"), it is determined that there is a jagged edge portion in the vertical direction, and the object pixel data 3D is determined to be black ("1"). The corresponding logical expression is given in Fig 21B. These logics can be applied to jagged edge portions symmetric along with the main scanning direction and the sub scanning direction. Note that in case the 3D data is initially depicted to be "black", it can be kept "black".

Thus jagged edge portions of a image in the dot pattern for recording density of 300 dpi as shown in Fig. 22A can be smoothed as in Fig. 22B by the combination of the aforementioned logics.

The <logical expression 1> in Fig. 12B and the logical expression in Fig. 13B include all the above logics. As shown in Figs. 23 and 24, the jagged edge portions of the letters "G" and "t" in Figs. 2 and 3 can be smoothed with the interpolation based on the <logical expression 1> and the logical expression in Fig. 13B, which makes use of the characteristic advantage of the dot pattern of 600 dpi.

According to the first embodiment, interpolation dot information in the main scanning direction and the information in the sub scanning direction are generated in accordance with the information of peripheral dots of a dot to be interpolated. The recording density of the interpolation dot information is higher than that of the input image data in a fixed ratio. The printer engine having a corresponding recording density records the image in accordance with the interpolation dot information. Even when application programs for lower recording densities are used, the dot information developed for the lower recording density can be converted to the dot information for higher recording density with a small memory, thus images of high quality recorded with a higher density can be obtained.

Next, when SEL = "1" holds, the logical expressions when SEL = "0" holds is logically ORed with a logical expression for diffusion of isolated black dots. The ORed <logical expression 2> is given in Fig. 12C. When SEL = "1" holds, the logic for smoothing can be applied to an image data having continuous dots such as a character and figure. In images processed with halftone processing such as Dither method and error diffusion method, isolated dots are also detected and diffused in

the dot pattern for higher recording density (600 dpi). In Fig. 12C, logical expressions for removing isolated dots is added to an expression when SEL = "0" holds.

For example, when the dot pattern (shown in Fig. 7) of an image processed with the Dither method for recording density of 300 dpi is converted to the dot pattern for recording density of 600 dpi using the above logical expression. In Fig. 25, isolated dots having dot size of 300 dpi can be divided into small dots of 600 dpi and diffused. As the isolated dots in the light portions of a half-tone image are minimized and diffused, the image quality of the light portions can be improved.

In accordance with a kind of image data described below, the logical selection signal SEL may be set to change over the interpolation logics.

In case where the image data such as character or figure does not include a pixel data expressed in only one dot, the SEL signal is set to "1" so that the smoothing for graphic patterns and figures and the dot diffusion for images processed with half-tone processing such as the Dither method are carried out. In case where the image data such as character or figure includes a pixel data expressed in only one dot, only the smoothing for graphic patterns and figures is carried out and the dot diffusion for half-tone image is not carried out.

[Second embodiment]

Figs. 26 to 29 show logical operations according to the second embodiment. In the second embodiment, the logical expression when SEL = 1 holds in the first embodiment is modified. In this case, logics for detection of isolated white dots and for diffusion of the isolated white dots are logically ORed to the logical expression of the first embodiment. Accordingly, isolated white dots (300 dpi) in a dark portion of Dither pattern as shown in Fig. 8 can be minimized and diffused in the dot pattern of 600 dpi, thus the image quality in the dark portions of half-tone image can be improved.

[Third Embodiment]

Fig. 30 is a block diagram which shows the structure of an image recording apparatus according to the third embodiment of the present invention. Fig. 31 is a block diagram which shows the structure of a decision circuit according to the third embodiment.

In Fig. 30, like reference numerals designate corresponding parts in the structure of Fig. 9, therefore explanations will be omitted. Each of decision circuits 115 and 116 according to the third embodiment has a counter 151 which receives the clock signal LCLK (Figs. 30 and 31) and controls outputs α, β in order of $\alpha = 0$, $\beta = 0 \rightarrow \alpha = 1$, $\beta = 0 \rightarrow \alpha = 0$, $\beta = 1 \rightarrow \alpha = 1$, $\beta = 1$, every N-time count of the clock signal LCLK. The predetermined number N is selected, e.g., as N = 8. In this case, the outputs α, β are changed in line with the above cycle, every eighth count of the LCLK signals. Shift registers

118 to 121 function similarly to the shift registers 18 to 21 in Fig. 11. Logical circuits 122 and 123 are based on the third embodiment.

The logical expressions for the logical circuit 122 (123) are given in Figs. 33 to 38. Fig. 32 illustrates the relation between an object pixel and peripheral pixels, and Figs. 33 to 38 showing corresponding logical expressions are correlated with Fig. 32, similarly to the first embodiment.

Figs. 33 to 38 show logical expressions based on the third embodiment, and Fig. 39 illustrates the distribution of dots according to the third embodiment.

The logical expressions in the third embodiment are modifications of the logical expression in Figs. 12B and 12C. When SEL = 0 holds, the same logical expressions as <logical expression 1> are selected (Fig. 33), and when SEL = 1 holds, <logical expressions 2> are selected (Figs. 34 to 38).

When SEL = 1 holds, the logical circuit 122 (123) ORs a smoothed data such as a text image and figure with a data where isolated black dots are diffused. At the diffusion of isolated black dots, as values of outputs α, β are changed, e.g., every the eighth clock signal LCLK count, the logical expressions for the diffusion are changed as $\gamma1 \rightarrow \gamma2 \rightarrow \gamma3 \rightarrow \gamma4 \rightarrow$ in accordance with the values of α, β. The corresponding logical expressions are given in Figs. 35 to 38.

According to the third embodiment, the regular distribution of the diffused dots in the first embodiment (Fig. 25) can be more irregular and inconspicuous (Fig. 39), which further improves the image quality. In addition, the diffusion of isolated white dots in the second embodiment can be improved in the third embodiment.

The counter 51 may be reset with the BD signal indicating the start of main scanning.

Further, an image recording apparatus for the present invention is not limited to a laser-beam printer which is employed in the above embodiments.

Each of isolated dots detected in the present invention is not limited to a dot size of 300 dpi and a couple of dots of 300 dpi may be detected as an isolated dot.

As described above, the present invention enables recording where data of graphic characters and figures are expressed smoothly, and enables improvement of image quality in images processed by half-tone processings such as Dither method.

The present invention may be applied to a system constituted by a plurality of apparatus or to a single apparatus. Further, it goes without saying that the invention is applicable also to a case where a program for implementing the invention is supplied to a system or apparatus.

The present invention is not limited to the above embodiments and various changes and modifications can be made within the scope of the present invention. Therefore, to apprise the public of the scope of the present invention, the following claims are made.

Claims

1. An image processing apparatus comprising:

memory means (6 to 10) for storing first image information corresponding to a first recording density;

pixel interpolation means (15,16) for, when said first image information is to be converted to second image information corresponding to a second recording density higher than said first recording density, determining a pixel data to be interpolated corresponding to the pixel position of said second image information, in accordance with said first image information stored by said memory means; and

smoothing means (15,16) for, when said pixel interpolation means determines that pixel data is to be interpolated, detecting a jagged edge portion in accordance with said first image information stored by said memory means and for, when said pixel data to be interpolated is determined, determining a value of said pixel data to be interpolated to smooth said jagged edge portion, characterised by further comprising:

predetermined pattern diffusion means (15,16) for, when said pixel interpolation means determines pixel data to be interpolated, detecting predetermined pattern data in accordance with said first image information stored by said memory means (6 to 10) and for, when said predetermined pattern is detected, determining a value of said pixel data to be interpolated so that the predetermined pattern data is diffused in said second image information.

2. An apparatus according to claim 1, further comprising expanding/compressing means (1,5) for expanding or compressing said first image information in a main scanning direction corresponding to said second recording density, said memory means (6,7,8,9,10) being arranged to store the image information expanded or compressed by said expanding/compressing means.

3. An apparatus according to claim 1 or 2, wherein said pixel interpolation means (15,16) is arranged to determine a pixel data to be interpolated corresponding to the pixel position of said second image information by carrying out predetermined logical operations on said first image information for plural lines stored by said memory means, with the logical operation for a main scanning direction being different from a logical operation for a sub scanning direction.

4. An apparatus according to claim 1, 2 or 3, wherein

said memory means (6,7,8,9,10) includes plural line memories for storing image information, the number of plural line memories being more than said pixel interpolation means needs to execute interpolation, arranged so that while image information are simultaneously read out from several of said plural line memories, the next image data is written into a line memory of the rest of said plural line memories.

5. An apparatus according to claim 1, 2, 3 or 4, wherein said predetermined pattern diffusion means (15,16) is arranged to detect said predetermined pattern data by carrying out a predetermined logical operation on image information for plural lines stored by said memory means, and when said predetermined pattern data is detected, to determine a value of said pixel data to be interpolated so as to diffuse said predetermined pattern.

6. An apparatus according to claim 5, wherein said predetermined pattern diffusion means (15,16) is arranged to determine logical expressions in a predetermined order and to carry out said predetermined logical operation in accordance with a selected one of the logical expressions.

7. An apparatus according to claim 6, further comprising count means (51) for counting the number of pixels interpolated by said pixel interpolation means; said predetermined pattern diffusion means (15,16) being arranged to change over said logical expression to another logical expression when the counting value of said count means reaches at a predetermined value.

8. An apparatus according to any one of the preceding claims, further comprising selection means for selecting either a first mode in which both said predetermined pattern diffusion means (15,16) and said smoothing means (15,16) are activated or a second mode in which only said smoothing means (15,16) is activated.

9. An image processing apparatus according to any one of the preceding claims, further comprising output means (17) for outputting said second image information generated by said pixel interpolation means (15,16), and either or both of said predetermined pattern diffusion (15,16) and smoothing means to a printer engine.

10. A printer comprising an image processing apparatus in accordance with any one of the preceding claims.

11. An image processing method comprising the steps of:

storing first image information corresponding to a first recording density;
determining a pixel data to be interpolated corresponding to the pixel position of a second image information when said first image information is to be converted to a second image information corresponding to a second recording density higher than said first recording density, in accordance with said stored first image; and
detecting a jagged edge portion in accordance with said stored first image information when said pixel data to be interpolated is determined, and determining a value of said pixel data to be interpolated so that said jagged edge portion can be smoothed when said jagged edge portion is detected;

characterised by:
detecting a predetermined pattern in accordance with said stored first image information when said pixel data to be interpolated is determined in said pixel interpolating step, and determining a value of said pixel data to be interpolated so that the predetermined pattern data can be diffused in said second image information when said predetermined pattern is detected.

12. A method according to claim 11, further comprising expanding or compressing said first image information in a main scanning direction corresponding to said second recording density and storing the expanded or compressed image information.

13. A method according to claim 11 or 12, which comprises determining a pixel data to be interpolated corresponding to the pixel position of said second image information by carrying out predetermined logical operations on plural stored lines of first image information, and carrying out a logical operation in a main scanning direction different from a logical operation in a sub scanning direction.

14. A method according to claim 11, 12 or 13, which comprises detecting said predetermined pattern data by carrying out a predetermined logical operation on plural stored lines of image information and, when said predetermined pattern data is detected, determining a value of said pixel data to be interpolated so as to diffuse said predetermined pattern.

15. A method according to claim 14, which comprises determining logical expressions in a predetermined order and carrying out said predetermined logical operation in accordance with a selected one of the logical expressions.

16. A method according to claim 15, further comprising

counting the number of interpolated pixels and changing over said logical expression to another logical expression when the count value reaches a predetermined value.

17. A method according to any one of claims 11 to 16, further comprising selecting either a first mode in which both said predetermined pattern diffusion and smoothing are activated or a second mode in which only smoothing is activated.

Patentansprüche

1. Bildverarbeitungseinrichtung mit

einem Speichermittel (6 bis 10) zum Speichern erster Bildinformationen entsprechend einer ersten Aufzeichnungsdichte,
einem Bildelement-Interpolationsmittel (15, 16), das, wenn die ersten Bildinformationen in zweite Bildinformationen entsprechend einer zweiten Aufzeichnungsdichte umzuwandeln sind, die höher als die erste Aufzeichnungsdichte ist, zu interpolierende Bildelementdaten entsprechend der Bildelementposition der zweiten Bildinformationen gemäß den in dem Speichermittel gespeicherten ersten Bildinformationen bestimmt,
einem Glättungsmittel (15, 16), das, wenn das Bildelement-Interpolationsmittel bestimmt, daß Bildelementdaten zu interpolieren sind, einen unebenen Randabschnitt gemäß den durch das Speichermittel gespeicherten ersten Bildinformationen erfaßt und, wenn die zu interpolierenden Bildelementdaten bestimmt sind, einen Wert der zu interpolierenden Bildelementdaten zur Glättung des unebenen Randabschnitts bestimmt,

gekennzeichnet durch
ein Mittel zur Streuung vorbestimmter Muster (15, 16), das, wenn das Bildelement-Interpolationsmittel zu interpolierende Bildelementdaten bestimmt, vorbestimmte Musterdaten gemäß den durch das Speichermittel (6 bis 10) gespeicherten ersten Bildinformationen erfaßt und, wenn das vorbestimmte Muster erfaßt ist, einen Wert der zu interpolierenden Bildelementdaten derart bestimmt, daß die vorbestimmten Musterdaten bei den zweiten Bildinformationen gestreut werden.

2. Einrichtung nach Anspruch 1,
gekennzeichnet durch
ein Expandierungs-/Komprimierungsmittel (1, 5) zur Expandierung oder Komprimierung der ersten Bildinformationen in der Hauptabtastrichtung entsprechend der zweiten Aufzeichnungsdichte,

wobei das Speichermittel (6, 7, 8, 9, 10) die durch das Expandierungs-/Komprimierungsmittel expandierten oder komprimierten Bildinformationen speichert.

3. Einrichtung nach Anspruch 1 oder 2,
dadurch gekennzeichnet, daß
das Bildelement-Interpolationsmittel (15, 16) zu interpolierende Bildelementdaten entsprechend der Bildelementposition der zweiten Bildinformation durch Ausführen vorbestimmter logischen Operationen an den ersten Bildinformationen für mehrere durch das Speichermittel gespeicherte Zeilen bestimmt, wobei sich die logische Operation für die Hauptabtastrichtung von einer logischen Operation für die Nebenabtastrichtung unterscheidet.

4. Einrichtung nach Anspruch 1, 2 oder 3,
dadurch gekennzeichnet, daß
das Speichermittel (6, 7, 8, 9, 10) mehrere Zeilenspeicher zum Speichern von Bildinformationen aufweist, wobei die Anzahl der mehreren Zeilenspeicher größer als für die Ausführung der Interpolation durch das Bildelement-Interpolationsmittel erforderlich ist und sie derart angeordnet sind, daß, während Bildinformationen gleichzeitig aus einigen der mehreren Zeilenspeicher ausgelesen werden, die nächsten Bilddaten in einen Zeilenspeicher der restlichen der mehreren Zeilenspeicher geschrieben werden.

5. Einrichtung nach einem der Ansprüche 1, 2, 3 oder 4,
dadurch gekennzeichnet, daß
das Mittel zur Streuung vorbestimmter Muster (15, 16) die vorbestimmten Musterdaten durch Ausführung einer vorbestimmten logischen Operation an Bildinformationen für mehrere durch das Speichermittel gespeicherten Zeilen erfaßt und, wenn die vorbestimmten Musterdaten erfaßt sind, einen Wert der zu interpolierenden Bildelementdaten zur Streuung des vorbestimmten Musters bestimmt.

6. Einrichtung nach Anspruch 5,
dadurch gekennzeichnet, daß
das Mittel zur Streuung vorbestimmter Muster (15, 16) logische Ausdrücke in einer vorbestimmten Reihenfolge bestimmt und die vorbestimmte logische Operation gemäß einem ausgewählten logischen Ausdruck ausführt.

7. Einrichtung nach Anspruch 6,
gekennzeichnet durch
ein Zählmittel (51) zum Zählen der Anzahl der durch das Bildelement-Interpolationsmittel interpolierten Bildelemente, wobei das Mittel zur Streuung vorbestimmter Muster (15, 16) von einem logischen Ausdruck zu einem anderen logischen Ausdruck

wechselt, wenn der Zählwert der Zähleinrichtung einen vorbestimmten Wert erreicht.

8. Einrichtung nach einem der vorangehenden Ansprüche,
   gekennzeichnet durch
   ein Auswählmittel zur Auswahl entweder einer ersten Betriebsart, bei der sowohl das Mittel zur Streuung vorbestimmter Muster (15, 16) als auch das Glättungsmittel (15, 16) betrieben werden, oder einer zweiten Betriebsart, bei der lediglich das Glättungsmittel (15, 16) betrieben wird.

9. Bildverarbeitungseinrichtung nach einem der vorangehenden Ansprüche,
   gekennzeichnet durch
   ein Ausgabemittel (17) zur Ausgabe der durch das Bildelement-Interpolationsmittel (15, 16) sowie durch das Mittel zur Streuung vorbestimmter Muster (15, 16) und/oder das Glättungsmittel erzeugten zweiten Bildinformationen an eine Druckmaschine.

10. Drucker mit einer Bildverarbeitungseinrichtung nach einem der vorangehenden Ansprüche.

11. Bildverarbeitungsverfahren mit den Schritten:

    Speichern erster Bildinformationen entsprechend einer ersten Bilddichte,
    Bestimmen von zu interpolierenden Bildelementdaten entsprechend der Bildelementposition von zweiten Bildinformationen gemäß dem gespeicherten ersten Bild, wenn die ersten Bildinformationen in zweite Bildinformationen entsprechend einer zweiten Aufzeichnungsdichte umzuwandeln sind, die höher als die erste Aufzeichnungsdichte ist, und
    Erfassen eines unebenen Randabschnitts entsprechend den gespeicherten ersten Bildinformationen, wenn die zu interpolierenden Bildelementdaten bestimmt sind, und Bestimmen eines Wertes der zu interpolierenden Bildelementdaten derart, daß der unebene Randabschnitt geglättet werden kann, wenn der unebene Randabschnitt erfaßt ist,

    gekennzeichnet durch
    Erfassen eines vorbestimmten Musters gemäß den gespeicherten ersten Bildinformationen, wenn die zu interpolierenden Bildelementdaten bei dem Bildelemt-Interpolationsschritt bestimmt sind, und Bestimmen eines Wertes der zu interpolierenden Bildelementdaten derart, daß die vorbestimmten Musterdaten bei den zweiten Bildinformationen gestreut werden können, wenn das vorbestimmte Muster erfaßt ist.

12. Verfahren nach Anspruch 11,
    gekennzeichnet durch
    Expandieren oder Komprimieren der ersten Bildinformationen in der Hauptabtastrichtung entsprechend der zweiten Aufzeichnungsdichte und Speichern der expandierten oder komprimierten Bildinformationen.

13. Verfahren nach Anspruch 11 oder 12,
    gekennzeichnet durch
    Bestimmen von zu interpolierenden Bildlementdaten entsprechend der Bildelementposition der zweiten Bildinformationen durch Ausführen vorbestimmter logischer Operationen an mehreren gespeicherten Zeilen der ersten Bildinformationen und Ausführen einer logischen Operationen in der Hauptabtastrichtung, die sich von einer logischen Operation in der Nebenabtastrichtung unterscheidet.

14. Verfahren nach Anspruch 11, 12 oder 13,
    gekennzeichnet durch
    Erfassen der vorbestimmten Musterdaten durch Ausführen einer vorbestimmten logischen Operation an mehreren gespeicherten Zeilen der Bildinformationen und, wenn die vorbestimmten Musterdaten erfaßt sind, Bestimmen eines Wertes der zu interpolierenden Bildelementdaten zur Streuung des vorbestimmten Musters.

15. Verfahren nach Anspruch 14,
    gekennzeichnet durch
    Bestimmen logischer Ausdrücke in einer vorbestimmten Reihenfolge und Ausführen der vorbestimmten logischen Operation gemäß einem ausgewählten logischen Ausdruck.

16. Verfahren nach Anspruch 15,
    gekennzeichnet durch
    Zählen der Anzahl interpolierten Bildelemente und Wechseln von dem logischen Ausdruck zu einem anderen logischen Ausdruck, wenn der Zählwert einen vorbestimmten Wert erreicht.

17. Verfahren nach einem der Ansprüche 11 bis 16,
    gekennzeichnet durch
    Auswählen entweder einer ersten Betriebsart, bei der sowohl die Streuung des vorbestimmten Musters als auch die Glättung betrieben werden, oder einer zweiten Betriebsart, bei der lediglich die Glättung betrieben wird.

Revendications

1. Appareil de traitement d'image comprenant:

   des moyens (6 à 10) formant mémoire pour

stocker une première information d'image correspondant à une première densité d'enregistrement;

des moyens (15, 16) d'interpolation de pixel pour déterminer, lorsque ladite première information d'image doit être convertie en une seconde information d'image correspondant à une seconde densité d'enregistrement supérieure à ladite première densité d'enregistrement, des données de pixel à interpoler correspondant à la position de pixel de ladite seconde information d'image, en fonction de ladite première information d'image stockée par lesdits moyens formant mémoire; et

des moyens de lissage (15, 16) pour détecter, lorsque ledit moyen d'interpolation de pixel détermine que des données de pixel doivent être interpolées, une partie de bord irrégulière en fonction de ladite première information d'image stockée par lesdits moyens formant mémoire et pour déterminer, lorsque lesdites données de pixel à interpoler sont déterminées, la valeur desdites données de pixel à interpoler afin de lisser ladite partie de bord irrégulière, caractérisé en ce qu'il comprend en outre:

des moyens (15, 16) de diffusion de configuration prédéterminée pour détecter, lorsque ledit moyen d'interpolation de pixel détermine des données de pixel à interpoler, des données de configuration prédéterminée en fonction de ladite première information d'image stockée par lesdits moyens formant mémoire (6 à 10) et pour déterminer, lorsque ladite configuration prédéterminée est détectée, la valeur desdites données de pixel à interpoler, de telle sorte que les données de configuration prédéterminée sont diffusées dans ladite seconde information d'image.

2. Appareil selon la revendication 1, comprenant en outre des moyens (1, 5) d'extension/compression pour étendre ou comprimer ladite première information d'image dans la direction de balayage principal correspondant à ladite seconde densité d'enregistrement, lesdits moyens formant mémoire (6, 7, 8, 9, 10) étant agencés pour stocker l'information d'image étendue ou comprimée par lesdits moyens d'extension/compression.

3. Appareil selon la revendication 1 ou 2, dans lequel lesdits moyens d'interpolation (15, 16) de pixel sont agencés pour déterminer des données de pixel à interpoler correspondant à la position de pixel de ladite seconde information d'image en effectuant des opérations logiques prédéterminées sur ladite première information d'image pour plusieurs lignes stockées par lesdits moyens formant mémoire, l'opération logique pour une la direction de balaya-

ge principal étant différente d'une opération logique pour une direction de balayage secondaire.

4. Appareil selon la revendication 1, 2 ou 3, dans lequel lesdits moyens (6, 7, 8, 9, 10) formant mémoire comportent plusieurs mémoires de ligne pour stocker une information d'image, le nombre de mémoires de ligne étant supérieur au nombre nécessité par lesdits moyens d'interpolation de pixel pour exécuter une interpolation, agencées de telle sorte que, tandis que les informations d'image sont lues simultanément à partir de plusieurs de ladite pluralité de mémoires de ligne, les données d'image suivantes sont écrites dans une mémoire de ligne desdites autres plusieurs mémoires de ligne.

5. Appareil selon la revendication 1, 2, 3 ou 4, dans lequel lesdits moyens (15, 16) de diffusion de configuration prédéterminée sont agencés pour détecter lesdites données de configuration prédéterminée en effectuant une opération logique prédéterminée sur une information d'image pour plusieurs lignes stockées par lesdits moyens formant mémoire, et pour déterminer, lorsque lesdites données de configuration prédéterminée sont détectées, la valeur desdites données de pixel à interpoler, de manière à diffuser ladite configuration prédéterminée.

6. Appareil selon la revendication 5, dans lequel lesdits moyens (15, 16) de diffusion de configuration prédéterminée sont agencés pour déterminer des expressions logiques dans un ordre prédéterminé et pour effectuer ladite opération logique prédéterminée en fonction d'une expression sélectionnée parmi les expressions logiques.

7. Appareil selon la revendication 6, comprenant en outre un moyen (51) de comptage pour compter le nombre de pixels interpolés par lesdits moyens d'interpolation de pixel, lesdits moyens (15, 16) de diffusion de configuration prédéterminée étant agencés pour faire passer ladite expression logique à une autre expression logique lorsque la valeur de comptage dudit moyen de comptage atteint une valeur prédéterminée.

8. Appareil selon l'une quelconque des revendications précédentes, comprenant en outre un moyen de sélection pour sélectionner, soit un premier mode dans lequel à la fois lesdits moyens (15, 16) de diffusion de configuration prédéterminée et lesdits moyens de lissage (15, 16) sont activés, soit un second mode dans lequel seuls lesdits moyens de lissage (15, 16) sont activés.

9. Appareil de traitement d'image selon l'une quelconque des revendications précédentes, comprenant en outre un moyen de sortie (17) pour délivrer, à un

mécanisme d'imprimante, ladite seconde informa-
tion d'image générée par lesdits moyens (15, 16)
d'interpolation de pixel, et l'un ou l'autre ou les deux
desdits moyens de diffusion (15, 16) de configura-
tion prédéterminée et de lissage .

10. Imprimante comprenant un appareil de traitement
d'image selon l'une quelconque des revendications
précédentes.

11. Procédé de traitement d'image comprenant les éta-
pes suivantes:

> stockage d'une première information d'image
> correspondant à une première densité d'enre-
> gistrement;
> détermination de données de pixel à interpoler
> correspondant à la position de pixel d'une se-
> conde information d'image lorsque ladite pre-
> mière information d'image doit être convertie
> en une seconde information d'image corres-
> pondant à une seconde densité d'enregistre-
> ment supérieure à ladite première densité d'en-
> registrement, en fonction de ladite première
> image stockée; et
> détection d'une partie de bord irrégulière en
> fonction de ladite première information d'image
> stockée lorsque lesdites données de pixel à in-
> terpoler sont déterminées, et détermination de
> la valeur desdites données de pixel à interpoler
> de telle sorte que ladite partie de bord irrégu-
> lière peut être lissée lorsque ladite partie de
> bord irrégulière est détectée;
>
> caractérisé par:
> la détection d'une configuration prédétermi-
> née en fonction de ladite première information
> d'image stockée lorsque lesdites données de pixel
> à interpoler sont déterminées au cours de ladite éta-
> pe d'interpolation de pixel, et détermination de la
> valeur desdites données de pixel à interpoler de tel-
> le sorte que les données de configuration prédéter-
> minée peuvent être diffusées dans ladite seconde
> information d'image lorsque ladite configuration
> prédéterminée est détectée.

12. Procédé selon la revendication 11, comprenant en
outre l'extension ou la compression de ladite pre-
mière information d'image dans une direction de ba-
layage principal correspondant à ladite seconde
densité d'enregistrement et stockage de l'informa-
tion d'image étendue ou comprimée.

13. Procédé selon la revendication 11 ou 12, compre-
nant la détermination de données de pixel à inter-
poler correspondant à la position de pixel de ladite
seconde information d'image par réalisation d'opé-
rations logiques prédéterminées sur plusieurs li-
gnes stockées de ladite première information d'ima-
ge, et réalisation d'une opération logique dans une
direction de balayage principal, différente d'une
opération logique dans une direction de balayage
secondaire.

14. Procédé selon la revendication 11, 12 ou 13, com-
prenant la détection desdites données de configu-
ration prédéterminée par réalisation d'une opéra-
tion logique prédéterminée sur plusieurs lignes
stockées d'une information d'image et, lorsque les-
dites données de configuration prédéterminée sont
détectées, détermination de la valeur desdites don-
nées de pixel à interpoler de manière à diffuser la-
dite configuration prédéterminée.

15. Procédé selon la revendication 14, comprenant la
détermination d'expressions logiques dans un or-
dre prédéterminé et la réalisation de ladite opéra-
tion logique prédéterminée en fonction d'une ex-
pression sélectionnée parmi les expressions logi-
ques.

16. Procédé selon la revendication 15, comprenant en
outre le comptage du nombre de pixels interpolés
et le passage de ladite expression logique à une
autre expression logique lorsque la valeur de comp-
te atteint une valeur prédéterminée.

17. Procédé selon l'une quelconque des revendications
11 à 16, comprenant en outre la sélection de l'un ou
l'autre d'un premier mode dans lequel, à la fois la-
dite diffusion de configuration prédéterminée et le
lissage sont activés, ou d'un second mode dans le-
quel seul le lissage est activé.
